(54) Title: MINIMALLY INVASIVE MEDICAL DEVICE DEPLOYMENT AND RETRIEVAL SYSTEM

(57) Abstract

The present invention provides a medical device retrieval system comprising a working element carried by a flexible, elongate shaft, the working element having a proximal profile and the shaft extending proximally from the working element and a retrieval cover slidably carried along the shaft of the medical device, the cover having a deployed configuration and being capable of being compressed into a compressed configuration for deployment, yet resiliently substantially return to the deployed configuration; the cover in its deployed configuration having a radially reduced proximal portion, a distally open distal end defining a distal opening having a maximum dimension at least as great as the maximum dimension of the proximal profile of the working element of the medical device, and an elongate internal recess defined between the proximal portion and the distal end.

## MINIMALLY INVASIVE MEDICAL DEVICE DEPLOYMENT AND RETRIEVAL SYSTEM

### FIELD OF THE INVENTION

The present invention generally relates to minimally invasive surgical procedures, e.g., angioplasty and atherectomy procedures, and has particular utility in connection with retrieving a medical device which has already been deployed. In one embodiment, the invention provides a vascular filter which can be retrieved with minimal risk of dumping the entrained contents back into the patient's bloodstream.

### BACKGROUND OF THE INVENTION

In some medical procedures, a minimally invasive medical device is used to capture or dislodge material from within a patient's vascular system or other body vessel. For example, in certain procedures, balloon catheters are positioned such that the deflated balloon is placed distally of a vascular occlusion. Typically these vascular occlusions are relatively soft, uncalcified deposited along the walls of an artery. The balloon then may be inflated and drawn proximally. This will tend to dislodge any atheromatous material and withdraw it proximally with the balloon. In current procedures, an aspiration catheter will be moved distally into position adjacent the balloon and will be used to aspirate the dislodged material from the vessel.

A number of other minimally invasive surgical procedures are being used to treat vascular occlusions. These procedures include rotational atherectomy and balloon angioplasty. With the increasing use of vascular stents, it has been discovered that tissue or other material may build up inside a stent, reducing the patency of the vessel through the stent. In the course of improving the patency of the blood vessel utilizing these techniques, there is a risk that the material which was formally causing the obstruction within the vessel can simply float downstream with the flow of blood to the vessel. Accordingly, there is an

5 increasing recognition of the value of taking steps to capture the dislodged material.

10 A number of researchers have proposed various traps or filters for capturing the particulate matter or other embolic particles let loose in such procedures. Some filters are permanently implanted within the vessel. Emboli  
15 trapped within the filter are either aspirated out of the interior of the filter or are dissolved using drugs. Other filters are intended to be temporary in nature, typically being removed after the angioplasty, atherectomy or other procedure is complete. Generally, the goal is to retract the filter with the thrombi trapped  
20 therein. Unfortunately, many designs of such temporary filters may get relatively difficult or complex to retract the trap back in to the catheter through which it was delivered without simply dumping the trapped thrombi back in to the bloodstream.

25 One particularly advantageous vascular filter is shown in co-pending U.S. Patent Application No. 08/272,425, and International Patent Application No. PCT/US95/08613, which was published as International Publication No. WO  
30 96/01591, the teachings of which are specifically incorporated herein by reference.

35 20 Figures 11-16 of WO 96/01591 are attached hereto as Figures 1-6 of the present application. Figure 1 is a vascular trap which is suitable for use in temporarily filtering embolic particles and the like from blood passing through a patient's vascular system. This device would most frequently be used to filter emboli from a patient's blood when another medical procedure is being  
40 performed, such as by using the trap in conjunction with a rotating cutting blade during an atherectomy, with a balloon catheter during angioplasty, or with a device used to clear the lumen of a stent during a stent cleaning procedure. It is  
45 to be understood, though, that the trap could also be used in other similar applications, such as in channels in patient's bodies other than their vascular systems.

50

55

5 The vascular trap 250 of Figures 1A and 1B comprises a generally  
umbrella-shaped basket 270 carried adjacent a distal end of a guidewire 260.  
The guidewire in this embodiment includes a tapered distal section 262 with a  
10 spirally wound coil 264 extending a distal length of the wire. Guidewires having  
such a distal end are conventional in the art. The basket 270 is positioned  
generally distally of the coil 264, and is desirably attached to the guidewire  
15 approximately with the proximal end of the tapered section as shown in these  
drawings.

The basket 270 of the device shown in WO 96/01591 (shown in its  
20 collapsed configuration in Figure 1A) includes a distal band 272 and a proximal  
band 274. The distal band may be made of a radiopaque material, such as  
gold, platinum or tungsten, and is affixed directly to the shaft of the guidewire  
260. This attachment may be made by any suitable means, such as by welding,  
25 brazing or soldering. Alternatively, the distal band 272 may comprise a bead of  
a biocompatible cementitious material, such as a curable organic resin. WO  
96/01591 teaches that a radiopaque metal or the like can be imbedded in the  
cementitious material to increase the visibility of the band for fluoroscopic  
30 observation. The proximal band 274 may be formed of a hypotube sized to  
permit the tube to slide along the guidewire during deployment. The inventors of  
that prior application suggest that the hypotube be made of a metallic material; a  
35 thin-walled tube of a NiTi alloy should suffice. If so desired, the proximal band  
may be formed of a more radiopaque metal, or a NiTi alloy band can have a  
radiopaque coating applied to its surface.

40 As taught in some detail in WO 96/01591, the basket 270 taught therein  
is formed of a metal fabric. The metal fabric of this embodiment is optimally  
25 initially formed as a tubular braid and the ends of the wires forming the braid can  
be attached together by means of the bands 272, 274 before the fabric is cut to  
45 length. These bands 272, 274 will help prevent the metal fabric from unraveling  
during the forming process. (The method of forming the basket 270 is described  
30 in great detail in WO 96/01591 and this process is still believed to provide a

5 suitable means for creating such a basket. The process is also discussed briefly below in connection with Figure 6.)

10 When the device is in its collapsed state for deployment in a patient's vessel (as illustrated in Figure 1A), the basket 270 of this device is said to be  
5 collapsed toward the axis of the guidewire 260. The distal 272 and proximal 274 bands are spaced away from one another along the length of the guidewire, with the fabric of the device extending therebetween. This publication teaches it is  
15 preferred that the basket is in its collapsed engaged the outer surface of the guidewire to permit the device to be deployed through a relatively small lumen of  
10 a catheter or another medical device.

20 When the device is deployed in a patient's vascular system, the basket will take on an expanded configuration wherein it extends outwardly of the outer surface of the guidewire. As best seen in Figure 1B, the shape of the basket  
25 270 when deployed may generally resemble a conventional umbrella or  
15 parachute, having a dome-like structure curving radially outwardly from the guidewire moving proximally from the distal band 272. It is to be understood that other suitable shapes could easily perform the desired filtering function, such as a conical shape wherein the slope of the device changes more linearly than the smooth, rounded version shown in Figure 1B. A relatively flat, disc  
30 shape may also suffice, but it is preferred that the device have a cavity or recess  
20 (discussed below) to better retain emboli or other material captured thereby. In this expanded configuration, the two bands 272, 274 are closer together, with the distal band 272 optimally being spaced only a short distance from the proximal band 274, as illustrated.

40 In moving from its collapsed state (Figure 1A) to its expanded state (Figure 1B), the metal fabric of this device turns in on itself, with a proximal portion 282 of the collapsed basket being received within the interior of a distal portion 284 of the collapsed basket. This produces a two-layered structure having a proximal lip 286 spaced radially outwardly of the guidewire, defining a  
45 proximally-facing cup-shaped cavity 288 of the basket. When blood (or any  
30 other fluid) flows through the basket in a distal direction, any particulate matter in  
50

the blood, e.g. emboli released into the bloodstream during atherectomy or angioplasty procedures, will tend to be trapped in the cavity 288 of the basket.

WO 96/01591 teaches that the precise dimensions of the metal fabric can be varied as desired for various applications. If the device 250 is to be used as a vascular filter to trap emboli released into the blood, for example, this reference teaches that the pores (i.e. the openings between the crossing metal strands) of the fabric are desirably on the order of about 1.0 mm. These inventors deemed this to be the minimum size of any particles which are likely to cause any adverse side effects if they are allowed to float freely within a blood vessel. They teach that the pores should not be too small, though, because the blood (or other fluid) should be free to pass through the wall of the basket 270. If so desired, the basket may be coated with a suitable anti-thrombogenic coating to prevent the basket from occluding a blood vessel in which it is deployed.

When a fabric having 1.0 mm pores is used to form this basket 270, the forming process reorients the wires relative to one another and in some areas (e.g. adjacent the proximal lip 286) the pores tend to be larger than 1.0 mm. However, because the basket's walls are formed of essentially two thicknesses 282, 284 of the fabric, the effective pore size of the device may be significantly reduced even at these locations.

The device 250 of Figures 11 is also provided with tethers 290 for collapsing the basket 270 during retraction. The basket may include four independent tether wires, each of which extends proximally from the proximal lip 286 of the deployed basket. The authors suggested, though, that the four tether wires illustrated in the drawings be formed of two longer wires, with each wire extending peripherally about a portion of the proximal lip of the basket. These tether wires may be intertwined with the wires of the metal fabric to keep the tethers in place during use. When such tethers are retracted or drawn down toward the guidewire, the wires extending along the proximal lip of the basket will tend to act as drawstrings, drawing the proximal end of the basket radially inwardly toward the guidewire. This tends to close the basket and entrap any

material caught in the cavity 288 of the basket during use so that the basket can be retracted without the use of a cover.

The tether wires 290 may extend along much of the length of the guidewire so that they will extend outside the patient's body during use of the device 250. When it is desired to collapse the basket for retrieval, the operator can simply hold the guidewire 260 steady and retract the tethers with respect to the guidewire. This can tend to be relatively cumbersome, though, and may be too difficult to effectively accomplish without breaking the tethers if the device is deployed at a selective site reached by a tortuous path, such as in the brain.

To address this issue, the authors suggest, as shown in Figures 1A and 1B, that the tethers 290 be attached to the guidewire 260 at a position spaced proximally of the basket. The tethers may, for example, be attached to a metal strap 292 or the like and this strap 292 may be affixed to the shaft of the guidewire. When it is desired to close the proximal end of the basket for retraction, they suggest urging an external catheter (not shown) distally toward the basket 270. When the catheter encounters the radially extending tethers, the distal end of the catheter will tend to draw the tethers toward the guidewire as the catheter is advanced, which will, in turn, tend to draw the proximal end of the basket closed.

Figures 2A and 2B illustrate an alternative embodiment of the device shown in Figures 1A and 1B, also in accordance with the teachings of WO 96/01591. Figure 2A shows the device collapsed in a catheter C for deployment while Figure 2B shows the device in its deployed configuration. In Figures 2A and 2B, the basket 270 is much the same as that outlined above in connection with Figures 1A and 1B. In the embodiment of Figures 12, though, the distal band 272 is affixed to the guidewire 260' at the distal tip of the guidewire. The guidewire 260' is of the type referred to in the art as a "movable core" guidewire. In such guidewires, a core wire 265 is received within the lumen of a helically wound wire coil 266 and the core wire 265 extends distally beyond the distal end of the coil 266. A thin, elongate safety wire 268 may extend along the entire lumen of the coil 266 and the distal end of the safety wire may be attached to

the distal end of the coil to prevent loss of a segment of the coil if the coil should break.

In the embodiment of Figures 1 A and 1B, the proximal ends of the tethers 290 are attached to a metal strap 292 which is itself attached the shaft of the guidewire 260. In Figures 2A and 2B, the tethers are not attached to the core wire 265 itself. Instead, the tethers are attached to the coil 266 of the guidewire. The tethers may be attached to the coil by any suitable means, such as by means of laser spot welding, soldering or brazing. The tethers 290 may be attached to the coil 266 at virtually an spot along the length of the coil. As illustrated in these drawings, for example, the tethers may be attached to the coil adjacent the coil's distal end. However, if so desired the tethers may be attached to the coil at a location space more proximally from the basket 270.

An external catheter such as that referred to in the discussion of Figures 1A, but not shown in that figure, is illustrated in Figures 2A and 2B. Once the basket 270 is deployed in a patient's vessel to substantially reach the expanded configuration shown in Figure 2B and the basket has performed its intended filtration function, the external catheter C can be urged distally toward the basket 270. As this catheter is urged forward, the tethers will tend to be drawn into the distal end of the catheter, which is substantially narrower than the proximal lip 286 of the basket. This will tend to draw the tethers down toward the guidewire and help close the basket, as explained above.

Figures 3-5 illustrate yet another alternative embodiment of a vascular trap in accordance with WO 96/01591. This vascular trap 300 includes a basket 320 received over a guidewire 310. In most respects, the basket 320 is directly analogous to the basket 270 illustrated in Figures 1-2. The basket 320 includes a proximal band 322 and a distal band 324. As in the device of Figures 2A and 2B, the distal band may be attached to the guidewire adjacent its distal end. If so desired, though, a structure such as is shown in Figures 1A and 1B, wherein the guidewire extends distally beyond the basket, could instead be used.

As best seen in its collapsed state (shown in Figure 3), the basket includes a distal segment 325 and a proximal segment 326, with the distal end

5 of the distal segment being attached to the distal band 324 and the proximal end  
of the proximal segment being attached to the proximal band 322. When the  
basket 320 is in its expanded configuration (shown in Figure 4), the proximal  
10 segment 326 is received within the distal segment 325, defining a proximal lip  
328 at the proximal edge of the device. The wall of the basket thus formed also  
includes a cavity 329 for trapping solids entrained in a fluid, such as emboli in a  
15 patient's blood stream.

The basket 320 of Figures 3-5 is also shaped a little bit differently than  
the basket 270 of the previous drawings. The primary difference between these  
20 two baskets is that the basket 320 is a little bit shorter along its axis than the  
basket 270. This different basket shape is simply intended to illustrate that the  
basket of a vascular trap in accordance with the invention can have any of a  
wide variety of shapes and no particular significance should be attached to the  
25 slightly different shapes shown in the various drawings.

15 In the vascular traps 250 and 250' of Figures 1 and 2, respectively,  
tethers were used to draw down the proximal end of the basket 270 to close the  
basket for retraction. In the embodiment shown in Figures 3-5, though, the trap  
300 includes a basket cover 340 positioned proximally of the basket 320. The  
basket cover may also be formed of a metallic tubular braid and is also adapted  
20 to be collapsed to lay generally along the outer surface of the guidewire 310.  
The cover 340 is not directly affixed to the guidewire at any point, though, but is  
instead intended to be slidable along the guidewire. As best seen in Figures 3  
and 4 wherein the cover is in its collapsed state, the cover 340 includes a distal  
hypotube 342 and a proximal control hypotube 344, with the distal hypotube  
40 being attached to the distal end of the cover 340 and the proximal control  
hypotube 344 being attached to the proximal end of the cover.

The cover 340 is shown in its deployed, expanded configuration in Figure  
45 5. As shown in that figure, the cover has a similar structure to that of the basket  
320, but is oriented to be open distally rather than proximally, as is the basket.  
30 As best seen in Figures 3 and 4 wherein the cover is in its collapsed state, the  
cover has a distal segment 352 and a proximal segment 354. When the cover is  
50

5 deployed by urging it distally out of the distal end of the deployment catheter C, the cover 340 will tend to resiliently return to its expanded configuration and the distal hypotube 342 will slide axially proximally along the guidewire toward the  
10 proximal control hypotube 344. This will invert the collapsed cover so that the  
5 distal section 352 is generally received within the proximal section 354, defining a distal lip 358 of the cover.

15 WO 96/01591 teaches that the proximal control hypotube 344 of this cover may extend along a substantial portion of the length of the catheter 310 so that it extends out of the patient's body when the device 300 is in place. By  
10 grasping the control hypotube and moving it relative to the guidewire 310, an operator can control the position of the cover 340 with respect to the basket 320,  
20 which is affixed to the guidewires. As explained in more detail below in connection with the use of the device 300, once the basket has been deployed and has been used to filter objects entrained in the fluid (e.g. emboli in blood),  
25 the cover 340 may be deployed and the trap may be drawn proximally toward the cover by moving the guidewire proximally with respect to the control hypotube 344.

30 The inner diameter of the distal lip 358 of the cover is desirably slightly larger than the outer diameter of the proximal lip 328 of the basket. Hence,  
20 when the basket is drawn proximally toward the cover it will be substantially enclosed therein. The cover will therefore tend to trap any emboli (not shown) or other particulate matter retained within the cavity 330 of the basket. A retrieval sheath S may then be urged distally to engage the outer surface of the cover  
35 340. This will tend to cause the cover to collapse about the basket, tightly  
40 engaging the outer surface of the basket. This somewhat collapsed structure can then be withdrawn from the patient's channel and removed from the patient's body. By enclosing the basket within the cover, the likelihood of any  
45 filtered debris within the basket being lost as the basket is retrieved will be substantially eliminated.

30 Figure 6 illustrates the molding element 370 suggested in WO 96/01591 for use in making a basket 270. Although the basket 320 and cover 340 of the  
50

5 trap 300 are shaped somewhat differently, an analogous molding element can  
be used for these portions of the trap 300 as well by simply modifying some of  
10 the dimensions of the molding element 370, but retaining the basic shape and  
structure of the molding element. It also should be understood that the molding  
5 element 370 is merely one possible molding element for forming a shape such  
as that of the basket 270 and WO 96/01591 teaches a variety of different  
molding elements and notes that other designs will be apparent to those skilled  
15 in the art.

The molding element 370 of Figure 6 has an outer molding section 372  
10 defining a curved inner surface 374 and an inner molding section 376 having an  
outer surface 378 substantially the same shape as the curved inner surface 374  
of the outer molding section. The inner molding section 376 should be sized to  
be received within the outer molding section, with a piece of the metal fabric (not  
20 shown) being disposed between the inner and outer molding sections. In a  
25 preferred embodiment, the inner surface 374 of the outer molding element and  
the outer surface 378 of the inner molding section each include a recess (375  
and 379, respectively) for receiving an end of the braid. The molding surface of  
30 this molding element 370, to which the fabric will generally conform, can be  
considered to include both the inner surface 374 of the outer molding section  
20 and the outer surface 378 of the inner molding section.

WO 96/01591 teaches that the two molding sections 372, 376 are spaced  
35 apart from one another and a length of a tubular braid of metal fabric (not shown  
in Figure 6) is disposed between these molding sections. Optimally, one end of  
the fabric is placed in the recess 375 of the outer molding section and the other  
40 end of the fabric is placed in the recess 379 in the inner molding section. As  
noted above, the ends of the tubular fabric can be clamped prior to this molding  
45 process to limit the likelihood that the fabric will unravel. The inner and outer  
molding sections can then be urged generally toward one another. As the ends  
of the wire approach one another, the tubular braid will tend to invert upon itself  
30 and a surface of the tubular braid will generally conform to either the inner  
surface 374 of the outer molding section or the outer surface 378 of the inner  
50

5 molding section, arriving at a shape analogous to that of the basket 270 of the  
traps 250, 250'. The two molding sections can then be locked in place with  
10 respect to one another and the metal fabric may be heat treated to set the wires  
in this deformed configuration.

5 This published international application also teaches how one may use  
the traps 250, 250' and 300 taught therein. It suggests that these traps be  
15 deployed for use in conjunction with another medical device and that they will  
most frequently be retracted from the patient's body after use. WO 96/01591  
uses a balloon angioplasty procedure and an atherectomy procedures as  
20 contexts for illustrating a method of using such traps. In balloon angioplasty,  
balloon catheters having inflatable balloons at their ends are positioned within a  
blood vessel so that the balloon is positioned within a stenosis. These balloons  
are positioned by tracking the balloon catheter along a guidewire or the like; the  
25 balloons typically have a central bore therethrough. Once the balloon is properly  
15 positioned, it is inflated and urges radially outwardly against the stenosis. This  
will tend to squeeze the stenosis against the walls of the vessel, improving  
patency of the vessel.

30 When the stenosis is treated in this fashion, though, there is a risk that  
some debris will break free and enter the blood flowing through the vessel. If left  
20 unchecked, this embolus can drift downstream and embolize a distal portion of  
the vessel. Depending on where the embolus comes to rest, the embolization  
35 can result in significant tissue or organ damage. In order to prevent, or at least  
substantially limit, such embolization, WO 96/01591 suggests the use of a  
vascular trap 250, 250' or 300 of with the balloon catheter. The device should  
40 be sized to permit it to be passed through the lumen of the particular balloon  
25 catheter to be used in the angioplasty.

45 In one method taught in WO 96/01591, the trap is deployed first. The  
basket (270 or 320) of the trap is guided to a position located downstream of the  
desired treatment site through an introduction catheter (e.g. the catheter C in  
30 Figures 12-15). The basket is then urged distally beyond the end of the  
catheter, which permits the basket to resiliently substantially return to its  
50

5 expanded configuration from its collapsed configuration within the catheter. Once the trap is in place, the balloon catheter can be exchanged for the  
10 introduction catheter, and the balloon catheter can track the guidewire (260 or 310) of the vascular trap. The balloon can then be positioned within the stenosis  
15 and expanded, as outlined above. Once the angioplasty has been completed, the balloon can be deflated again and withdrawn proximally out of the patient.

15 WO 96/01591 also explains that the balloon catheter can be used to perform the same function as performed by the introduction catheter in the preceding embodiment. In this embodiment, the balloon catheter is positioned  
20 in the patient's vessel so that the distal end of the balloon catheter is located downstream of the stenosis. The vascular trap (250, 250' or 300) of the invention is then passed through the lumen of the balloon catheter and the basket is urged out of the distal end of the catheter. The basket will resiliently  
25 substantially return to its preferred expanded configuration, whereupon the balloon catheter can be retracted along the shaft of the device's guidewire until  
30 the balloon is properly positioned within the stenosis.

30 If so desired, the balloon catheter can instead be provided with a length of standard catheter extending distally beyond the distal end of the balloon. The balloon can then be positioned within the stenosis and the basket can be urged  
35 out of the distal end of the distal extension of the catheter. In such an embodiment, the length of the distal extension of the catheter should be sufficient to properly position the basket with respect to the balloon when the basket exits the distal end of the catheter. This will eliminate the need to  
40 perform the separate step of retracting the balloon into position within the stenosis after the basket is deployed. The balloon can then be expanded,  
45 deflated and withdrawn as described above.

45 WO 96/01591 teaches that much the same procedure can be used to deploy a vascular trap for use in an atherectomy procedure. In such procedures, a cutting head is positioned at the distal end of an elongate, hollow  
50 shaft and the cutting head has a bore extending therethrough. The trap can be deployed in either of the methods outlined above, but it is anticipated that in

5 most instances the first procedure will be used, i.e. the basket will be deployed  
with an introduction catheter, which will be removed so that the cutting device  
can be guided over the guidewire of the vascular trap. This publication also  
10 stresses that the device 250, 250' and 300 could be used in other medical  
5 procedures in other bodily channels besides a patient's vascular system.

15 Since the trap is positioned downstream of the stenosis, any debris  
released during one of these procedures will tend to drift distally toward the  
basket and be caught therein. In order to prevent any emboli from simply  
floating past the trap, it is preferred that the proximal lip (288 or 328) of the  
20 10 basket be at least as large as the lumen of the vessel. WO 96/01591 suggests  
that the natural dimension of the proximal lip (i.e. where the basket has fully  
returned to its expanded configuration) be made somewhat greater than the  
vessel's inner diameter so the basket will firmly engage the wall of the vessel.

25 The method of retracting the basket will depend on which embodiment of  
15 the vascular trap is used, namely whether or not the device includes a cover  
340. The device 250 or 250' of Figures 1 or 2, respectively, do not include such  
a cover. However, they do include tethers 290 which extend proximally from the  
30 proximal lip 288 of the basket to an attachment to the guidewire. In either of  
these embodiments, a retrieval catheter can be introduced over the guidewire  
20 and urged distally toward the basket. As explained above in connection with  
Figures 1 and 2, this will tend to draw the tethers down toward the guidewire,  
effectively closing the proximal end of the basket 270. Once the basket is  
35 sufficiently closed, such as when the proximal lip of the basket engages the  
distal tip of the retrieval catheter, the catheter and the vascular trap can be  
40 25 retracted together from the patient's body. By substantially closing the proximal  
end of the basket in such a fashion, any emboli which are captured in the basket  
when it is deployed can be retained within the basket until it is removed from the  
45 patient's body.

50 If so desired, a balloon catheter or like device can instead be used, with  
30 the balloon catheter being used to draw down the tethers 290 and collapse the  
basket. The vascular trap can then be withdrawn with the balloon catheter

5 rather than having to separately introduce a removal catheter to remove the trap.

10 In withdrawing the embodiment illustrated in Figures 3-5, the cover 340 is positioned over the proximal lip of the basket before the vascular trap 300 is  
5 retracted. Once the medical procedure is completed and any debris has been captured in the basket, the cover 340 is allowed to resiliently substantially return to its expanded configuration. Once it is deployed proximally of the basket, the  
15 basket 320 can be drawn proximally toward the cover 340 until it engages or is received within the cover, as noted above in connection with Figure 5.

20 In actuality, the cover 340 of Figures 3-5 may be unable to return to its full expanded configuration due to the confines of the vessel in which it is deployed. As explained previously, the cover 340 is desirably larger than the basket 320 so that the basket can be received within the cover. However, the basket is  
25 optimally sized to engage the walls of the vessel to prevent the unwanted passage of emboli or other debris around the edges of the basket. Accordingly, the distal lip 358 of the cover will engage the wall of the channel before it expands to its full size. The walls of most bodily channels, such as blood  
30 vessels, tend to be somewhat elastic, though. The cover 340 will therefore tend to urge harder against the wall of the vessel than the smaller basket and may stretch the vessel a little bit more than will the basket. In this fashion, the cover  
20 may still be able to expand to a dimension large enough to permit the basket to be received in the cavity 356 of the cover. If not, the distal lip 358 of the cover can simply be brought into close engagement with the proximal lip 328 of the  
35 basket to generally seal the basket.

40 Once the cover 340 is brought into engagement with the basket 320, whether by receiving the basket within the cover or, less preferably, by engaging the lips 358, 328 of the cover and the basket, the device can be withdrawn  
45 proximally from the patient's vascular system. The cover will tend to prevent any emboli caught in the basket during deployment from being inadvertently lost  
30 during withdrawal.

15

5 The vascular traps 250, 250' and 300 shown in Figures 1-6 represent a  
significant advancement over previously available devices. The embodiment of  
10 Figures 3-5 shows particular promise in that the cover permits the user to  
withdraw the basket with the emboli entrained therein without having to take any  
5 additional precautions to minimize the chances that these emboli will be  
accidentally dumped back into the bloodstream.

### 15 SUMMARY OF THE INVENTION

The present invention provides a medical device retrieval system and a  
20 method of retrieving a medical device. In accordance with one embodiment of  
10 the invention, a medical device retrieval system includes a medical device and a  
retrieval cover. The medical device comprises a working element carried by a  
flexible, elongate shaft. The working element has a proximal profile and the  
25 shaft extends proximally from the working element. The retrieval cover is  
slidably carried along the shaft of the medical device. The cover has a deployed  
15 configuration and is capable of being compressed in a compressed configuration  
for deployment, yet resiliently substantially returned to the deployed  
30 configuration. The cover in its deployed configuration has a radially reduced  
proximal portion. A distally open distal end defining a distal opening having a  
maximum dimension at least as great as the maximum dimension on the  
35 proximal profile of the working element of the medical device, and an elongate  
20 internal recess defined between the proximal portion on the distal end. The  
cover in its compressed configuration is radially compressed inwardly toward the  
shaft and is distally open, with the distal end defining the distal-most portion of  
40 the cover. Optimally, the retrieval cover is designed to maintain this general  
25 orientation wherein the distal end of the device is always the distal-most portion  
of the cover, regardless of the configuration of the device.

45 This medical device retrieval system may further include a retrieval  
sheath which is slidable along the shaft of the medical device. Such a sheath, if  
50 included, is desirably positioned distally on the cover when the cover is in its  
30 deployed configuration. This retrieval sheath may have an inner diameter

55

5 smaller than the outer diameter of the cover in its deployed configuration. This sheath is adapted to slide distally along the cover to compress the cover about the medical device.

10 In accordance with a further embodiment, the present invention provides  
5 a medical device retrieval system which comprises a medical device, a retrieval sheath, a deployment stylet and a retrieval cover. The medical device  
15 comprises a working element carried by a flexible, elongate shaft having an outer diameter. The working element has a proximal profile and the shaft  
20 extends proximally from the working element. The retrieval sheath is slidable  
10 along the shaft of the medical device and optimally has a beveled distal end with a distal lumen. The deployment stylet is slidable along the shaft of the medical  
25 device and has a distal tip. This distal tip tapers distally from a first diameter approximating the diameter of the distal lumen of the sheath to a second  
15 diameter more closely approximating the outer diameter of the medical device  
shaft. This provides a transition between the shaft of the medical device and the  
30 distal end of the retrieval sheath when the deployment stylet is positioned such that a distal tip extends distally beyond the distal end of the retrieval sheath.  
The retrieval cover is slidable along the shaft of the medical device and is  
exchangeable for the stylet along that shaft. The cover has a deployed  
20 configuration and is capable of being compressed into a compressed  
35 configuration for sliding within the lumen of the retrieval sheath yet resiliently substantially return to the deployed configuration. In its deployed configuration,  
the cover has a radially reduced proximal portion, a distally open distal end, and  
40 an elongate internal recess defined between the proximal portion and the distal  
25 end. The distal end defines a distal opening having a maximum dimension at  
least as great as the maximum dimension of the proximal profile of the working  
45 element of the medical device. In its compressed configuration, the cover is  
radially compressed inwardly toward the shaft and is distally open, with the distal  
end defining the distal-most portion of the cover.

30 Another embodiment of the invention provides a retractable medical  
50 device system including a medical device, a retrieval cover and a retrieval

5 sheath. The medical device comprises a working element carried by a flexible, elongate shaft. The retrieval cover is slidable along the shaft of the medical device. The cover has a radially reduced proximal portion, a distally open distal end and an elongate tubular wall extending therebetween and defining a recess.  
10 The working element of the medical device is completely retained within the recess of the cover such that the tubular wall extends distally beyond the medical device. The retrieval sheath has a lumen and is slidable with respect to both the medical device and the cover. At least a proximal length of the working element of the medical device and the cover are retained within the lumen of the retrieval sheath, with the retrieval sheath regularly compressing the proximal length of the cover such that an intermediate portion of the wall tightly engages the surface of the medical device. This will tend to effectively trap any emboli or other materials retained by the medical device.

25 As noted above, the present invention contemplates a method. One such method involves receiving particulate or other form material within a channel of a patient's body. As a first step in performing this method, one provides a medical device having a working element and a flexible, elongate shaft adapted to follow a path within the channel; a distally open cover slidable with respect to the shaft; and a retrieval sheath movable with respect to the cover on the shaft. The medical device is positioned within the vessel to engage a wall of the channel and trap the material within the channel. Either during such positioning or after the medical device has been positioned and while it is trapping material within the channel, the cover and the retrieval sheath may be positioned so they are spaced proximally of the working element along the shaft of the medical device.  
40 The cover is radially compressed within the lumen of the retrieval sheath such that it has a distally open distal end and a wall defining a recess, the wall engaging an inner surface of the retrieval sheath. The cover is moved distally with respect to the retrieval sheath, thereby permitting the cover to radially expand into a deployed configuration wherein the distal end remains distally open and the enclosure is radially expanded. The cover expands radially outwardly into the deployed configuration without having to invert on itself. The

cover is then moved distally into engagement with a surface of the medical device to form therebetween an enclosure. The retrieval sheath may then be moved distally with respect to the cover to urge the cover to collapse about the medical device and tightly engage the surface of the medical device.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A is a schematic side view in accordance with WO 96/01591, showing a vascular trap in a collapsed state for deployment in a patient's vascular system;

Figure 1B is a schematic side view of the medical device of Figure 1A in an expanded state for deployment in a patient's vascular system;

Figure 2A is a schematic side view in accordance with WO 96/01591, showing an alternative vascular trap in a collapsed state within a catheter for deployment;

Figure 2B is a schematic side view of the device of Figure 2A, showing the device deployed distally of the catheter;

Figure 3 is a schematic perspective view in accordance with WO 96/01591 showing a vascular trap and a cover, both of which are collapsed within a catheter for deployment in a channel in a patient's body;

Figure 4 is a schematic side view of the device of Figure 3 in a partially deployed state, wherein the vascular trap has been deployed, but the cover is still collapsed within the catheter;

Figure 5 is a schematic side view of the device of Figure 3 in a fully deployed state;

Figure 6 illustrates one embodiment of a molding element which may be used in making a portion of the vascular traps shown in Figures 1-5;

Figure 7 is a schematic illustration of a retrieval sheath catching on a vascular obstruction proximally of the desired distal deployment site;

Figure 8 is a schematic side view of a device in accordance with the present invention with both the trap and the cover fully deployed;

Figure 9 is a schematic cross sectional view showing the device of Figure 8 wherein the trap has been deployed but the cover has retained within the retrieval sheath;

Figure 10 is a schematic illustration showing the invention deployed within a patient's vessel and having emboli retained therein;

Figure 11 is view similar to Figure 10, but showing the trap being retracted into the confines of the cover;

Figure 12 is a schematic, partially cut away view of the device of Figures 10 and 11 showing the cover being retracted within the retrieval sheath;

Figure 13 is a schematic partial cross sectional view of a distal portion of a medical device retrieval system of the invention utilizing a deployment stylet; and

Figure 14 is a schematic side view of a distal length of an alternative retrieval sheath for use with the invention.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Figures 8-12 schematically illustrate the operation of one embodiment of the present invention. Figure 8 illustrates certain operative portions of the medical device retrieval system 10 of the invention in a fully deployed state. As noted above, the retrieval system of the invention is intended to be used in connection with a medical device having a working element carried by flexible, elongate shaft. In these drawings, the medical device is typified as a vascular trap similar to the vascular trap 250 of Figure 11, but omitting the tethers 290. The working element of this medical device is a basket 12, which may be substantially as outlined above in connection with the description of the basket 270. The shaft in this design may simply comprise a guidewire 14. While the construction and operation of the basket 12 may be substantially the same as

20

that outline for the baskets shown in Figures 1-5, it is generally preferred that the proximal band 13 of this basket be attached to the guidewire while the distal band 15 be permitted to slide along the guidewire. Hence, when the basket 12 is released from a delivery catheter and the basket is allowed to achieve a radially expanded configuration, the distal end of the collapsed device (272 in Figure 1A) will slide approximately toward the proximal end (274) of the collapsed device.

It should be recognized that the medical device can be varied as desired. For example, the medical device used in connection with the present retrieval system could instead be a balloon catheter, wherein the working element would be the balloon portion of the catheter and the shaft would comprise the body of the catheter extending proximally of the balloon.

The other elements of the retrieval system 10 generally comprise a retrieval sheath 20 and a cover 30. It is to be understood that these drawings are intended merely for illustrative purposes and are not drawn to scale. In actual operation, the retrieval sheath 20 and the shaft 40 of the cover would likely be much smaller. These elements are simply drawn larger to make the various components easier to see in the attached illustrations.

The cover 30 includes a radially expandable body 31 carried by a shaft 40. The body has a proximal portion 32 which is radially compressed into close proximity with the shaft 40 and is desirably attached directly thereto. A tubular wall 34 extends distally from the proximal portion and terminates in a distally open end 36. The body 31 defines a recess 38 within which the working element of the medical device may be retracted, as explained more fully below. The majority of the length of this recess is defined by the generally tubular wall 34.

This radially expandable body 31 can be formed of any suitable material. As explained more fully below, it is preferred that this body be capable of being collapsed within the retrieval sheath 20 for deployment, radially expand into a deployed configuration, yet be readily collapsed by the retrieval sheath to tightly

engage the working element of the medical device. Any material which achieves this function may be used.

In one embodiment (not shown), the body 31 is formed of a flexible plastic material, which may be reinforced with one or more flexible metal hoops or the like to bias the tubular plastic member into a funnel-like configuration.

The illustrated embodiment is shown as comprising a series of flexible metal wires. As explained in some detail in International Publication No. WO 96/01591, such a radially expandable device may be made rather conveniently utilizing a metal fabric having strands formed of a material which is both resilient and which can be heat treated to substantially set a desired shape. Materials such as elgiloy, hastelloy, incoloy, certain grades of stainless steel and shape memory alloys. Of these materials, shape memory alloy such as nitinol are particularly preferred.

In one useful embodiment, the radially expandable body 31 is formed using the techniques outlined in WO 96/01591, starting with a metal fabric comprising both nitinol and platinum. For example, the fabric may be a generally tubular fabric formed of 48 wires having a diameter on the order of about 0.0015 inches and a pic rate of about 80-100 pics per inch. Of the 48 wires used to form this metal fabric, a relatively small percentage of the wires (e.g. 4-6 wires) may be formed of platinum or some other relatively radiopaque material to enhance visibility of the device on a fluoroscope without unduly affecting the resiliency of the fabric. If so desired, the wires can be coated with a therapeutic agent or with an antithrombogenic material. For example, the wires may be coated with heparin or with a known platelet-deactivating drug, e.g., a 2B-3A antagonist.

This radially expandable body 31 is carried by a axially slidable shaft 40. This shaft may take the form of a metallic hypotube, such as that discussed in connection with the embodiment of Figures 3-5. More preferably, though, the shaft 40 comprises a flexible plastic material of the type that is commonly used in forming medical catheters. If friction of this shaft 40 with the retrieval sheath

20 and/or the shaft 14 of the medical device is anticipated to present a problem, this shaft 40 of the cover may be formed of polytetrafluoroethylene or another suitable low-friction material.

The radially expandable body 31 may be attached to the shaft 40 in any suitable manner. Presumably, the ends of the wires defining the body 31 could be simply cast into the plastic defining the flexible shaft 40. However, the embodiment shown in the drawings is somewhat easier to make, utilizing a pair of marker bands 46 and 48 to attach the body to the shaft by clamping the proximal end about the exterior of the sheath. Forming these clamps of a radiopaque material will make it easier to track the position of the cover 30 as it is deployed. In the illustrated embodiment, the cover comprises an exterior layer and an interior layer of the metal fabric, much like the basket 270 described above in connection with Figures 1-5. In this configuration, the proximal marker band 46 may be used to clamp the exterior layer of the metal fabric to the exterior of the shaft 40 while the distal marker band 48 is used to clamp the interior layer of the fabric to the shaft.

In the illustrated embodiment, the shaft 40 includes a lumen 44 through which the shaft 14 of the medical device is received, thereby permitting the cover 30 to track that shaft for deployment. The shaft 40 shown in Figures 8 and 9 extends distally beyond the distal marker band 48 such that the distal tip 42 of the shaft is received within the recess 38 of the cover. Not only will this make manufacturing easier, but it will reduce the likelihood that any guidewire or other device passing through the lumen 44 of the shaft 40 will get caught up in the metal fabric defining the radially expandable body 31.

The retrieval sheath 20 may simply take the form of a standard medical catheter, with a tip as described below. This sheath has a generally tubular wall defining a lumen 24 within which the shaft 14 of the medical device and the shaft 40 of the cover may be slidably received. The differences in the diameters of these three elements 20, 40 and 14 are exaggerated in Figures 8 and 9 to

5 illustrate operation of the device. In reality, these diameters would likely be substantially closer than those shown.

10 The distal tip 22 of the retrieval sheath 20 may be beveled to produce a smoother tip. (The advantage of this tip construction will be highlighted below in connection with the discussion of Figures 7, 13 and 14.) If so desired, a marker  
15 band 26 may be incorporated into the wall of the retrieval sheath 20 adjacent the distal tip 22. This will help an operator visualize the relative position of the retrieval sheath 20, the cover 30 and the basket 12 during operation.

20 Figure 9 is a schematic cross sectional view of the device illustrated in Figure 8 prior to deployment of the cover. In operation, the medical device will typically be put in place first. As outlined above in connection with Figures 1 and 2, the basket 12 may be positioned distally of a particular treatment site and the treatment device (e.g. a balloon catheter or an atherectomy device) can be  
25 guided over the shaft 14 of the trap to perform the intended procedure. In the use of the retrieval system of the invention with such a trap, one would typically  
30 deploy the retrieval sheath 20 and the cover 30 after the basket 12 has been in place for some time rather than deploying all three elements at substantially the same time. It should be understood, though, that simultaneous deployment may be appropriate in other circumstances, such as when a cover 30 and retrieval  
35 sheath 20 are used in connection with a Foley catheter or the like.

40 Whereas Figure 8 illustrates the cover in its deployed configuration, Figure 9 illustrates the cover in a compressed configuration which is suitable for deployment. Even in its compressed configuration, it can be seen that the body 31 of the catheter generally includes a radially reduced proximal portion 32, an  
45 elongate tubular wall 34 and a distally open distal end 36 which defines the distal-most portion of the cover. This is indirect contrast to the structure shown in Figures 3 and 4, which show the cover 340 of that device in its collapsed state. In this collapsed state, the cover 340 has a distal segment 352 and a proximal segment 354, both of which are generally tubular in shape and lie  
50 proximate the exterior surface of the guide wire 310. Once this cover is

5 deployed as shown in Figure 5, though, the cover must invert on itself to position  
the distal section 352 generally within the proximal section 354 to define a distal  
lip 358 of the cover. This distal lip 358 is merely an intermediate point along the  
10 longer, axially expanded configuration of the device when it is collapsed, as  
shown in Figures 3 and 4.

There are a number of advantages of the structure of the present cover  
15 30 over the mechanically more complex design of Figures 3-5. In the cover 340  
of Figures 3-5, the cover must invert on itself before it can be used to enclose  
the basket 320. The resilient nature of the metal fabric used to form the cover  
20 340 will tend to resiliently draw the distal hypotube 342 proximally toward the  
proximal control hypotube 344 once the constraint of the deployment catheter C  
has been removed.

The walls of the vessel can hinder complete inversion of the cover 340,  
25 though. In particular, if the inner diameter of the vessel within which the cover is  
to be deployed is significantly smaller than the outer diameter of the fully  
15 deployed cover, the cover may take on a sausage-like configuration, with the  
distal and proximal segments 352, 354 of the cover expanding into engagement  
30 with the wall of the vessel, but being unable to expand sufficiently to allow the  
distal hypotube to invert the distal segment 352 so that it may be received within  
the proximal section 354. In such a circumstance, the cover will not define a  
35 suitable recess for receiving the basket 320 therein.

The design shown in Figures 8-12 does not require that the radially  
40 expandable body 31 invert on itself to reach its fully deployed configuration.  
Instead, the recess 38 will always remain in place. Deployment of the body 31  
25 distally beyond the distal tip 22 of the retrieval sheath will simply allow this  
recess to expand to a size wherein it may readily receive the working element of  
45 the medical device with which the cover is used.

While Figures 8 and 9 schematically illustrate the structure of the device  
and its various elements, Figures 10-12 are intended to schematically illustrate  
50 30 the manner in which the cover 30 may be used to retrieve a basket 12 which is

25

5 full of emboli or other particular material. In Figure 10, the deployment catheter  
C (discussed above in connection with Figures 1-5) is shown extending into the  
10 lumen of the vessel and terminating proximally of the position of the basket 12.  
The cavity of the basket 12 is filled with emboli E. If one were to simply pull the  
5 guidewire 12 proximally, this will tend to evert the generally umbrella-shaped  
basket 12, raising the possibility that the emboli E could be dumped into the  
15 bloodstream of the vessel.

In Figure 10, the retrieval sheath 20 is positioned proximally of the basket  
12, leaving a space between the distal tip 22 of the sheath 20 and the basket  
20 12. In this Figure, the cover 30 is still within the lumen 24 of the retrieval sheath  
20, much as in the configuration shown in cross section in Figure 9.

Once the retrieval sheath, with the cover retained therein, is properly  
25 positioned, the shaft 40 of the cover 30 may be advanced distally with respect to  
the sheath 20. This may be accomplished either by holding the sheath 20  
15 stationary and advancing the shaft 40 of the cover distally or by holding the shaft  
40 of the cover relatively stationary and withdrawing the retrieval sheath 20  
30 proximally to expose the readily expandable body 31 beyond the distal tip 22 of  
the sheath 20.

When the body 31 of the cover exits the distal end of the retrieval sheath  
35 20, it will tend to resiliently substantially return to the configuration schematically  
illustrated in Figure 8. Unlike the cover 340 of Figures 3-5, the body 31 of the  
present invention will begin to radially expand into its final shape as soon as the  
40 distal end 36 clears the distal tip 22 of the sheath 20. Accordingly, there is no  
need to deploy the cover 30 so that even the proximal marker band 46 is  
25 positioned distally of the distal tip 22 of the retrieval sheath as shown in Figure  
8. Instead, the proximal portion 32 of the body 31 may remain within the lumen  
45 of the retrieval sheath 20, as suggested in Figure 11, without compromising  
operation of the cover 30.

Figure 11 illustrates the device wherein the cover has been sufficiently  
50 30 deployed to define a recess large enough to receive the body of the basket 12.

55

5           therein. To achieve the configuration shown in Figure 11, the shaft 14 of the  
vascular trap is withdrawn proximally, drawing the basket 12 within the  
enclosure 38.

10           As noted above in connection with Figure 8, the presently preferred  
5       embodiment of such vascular trap employs a proximal band 13 which attaches a  
proximal end of the metal fabric defining the basket directly to the shaft of the  
15       guidewire 14 while the distal connector 15 is allowed to slide along the length of  
the shaft 14. Accordingly, when the operator pulls proximally on the guidewire  
14, this will tend to elongate the trap and cause it to evert. In the absence of  
20       aspiration or a cover 30, this could present some difficulties.

25           Prior to withdrawing the shaft 14 proximally, the distal end 36 of the cover  
is desirably brought immediately adjacent the basket 12. In a preferred  
embodiment, the distal end 36 of the body 31 of the cover defines a distal  
25       opening having a maximum dimension which is at least as great as the  
15       maximum dimension of the proximal profile of the basket 12, i.e., the maximum  
dimension of the proximal projection of the deployed basket. If the vessel is  
30       large enough, this would permit the cover to simply slide around the basket 12  
without significantly stressing the basket and causing it to collapse in any way.  
More likely than not, though, there will be insufficient clearance between the  
35       basket 12 and the wall of the vessel to permit the cover to readily slide between  
the vessel and the basket. Accordingly, the distal end of the cover will typically  
be brought into engagement with a surface of the basket 12. This will form  
40       between the cover and the basket and enclosure that includes both the cavity of  
the basket and the recess 38 of the cover. This movement of the cover distally  
25       into engagement with the medical device may be achieved either by actually  
physically moving the cover distally in an absolute sense, or simply withdrawing  
45       the basket 12 toward the cover which will effectively move the cover distally with  
respect to the medical device.

50           Figure 11 illustrates the relative positions of the elements of the invention  
30       if the operator continues to withdraw the guidewire 14 proximally after the cover

5 initially engages the surface of the basket 12. The basket has started to evert  
into a more oblong shape rather than the umbrella-shape shown in Figure 10.  
Nonetheless, the emboli still are retained within the enclosure defined by the  
10 cover and the basket.

5 In one preferred embodiment, the body 31 of the cover is at least as long  
as the working element of the medical device which is to be retrieved therewith.  
15 This permits the working element to be entirely enclosed by the cover during the  
retrieval process, enhancing the likelihood of a successful retrieval without  
inadvertent dumping of the matter captured by the medical device back into the  
20 patient's body. While the cover can be little longer than the working element of  
the medical device, it is anticipated that the cover may be significantly longer  
than that working element. This will permit an operator greater flexibility in using  
the device without adding unduly to the cost.

25 Figure 12 schematically illustrates the next stage of the method of  
15 removing the medical device from the patient's vascular system. In this view,  
the retrieval sheath has been moved distally with respect to the cover. As  
suggested above, this may be achieved either by moving the retrieval sheath  
30 distally along the cover or by withdrawing the cover (and, optimally, the medical  
device) proximally while holding the retrieval sheath 20 stationary. Urging the  
20 retrieval sheath distally with respect to the cover urges the cover to collapse  
about the medical device received therein. This causes the cover to tightly  
engage the surface of the medical device, helping better encase any particular  
35 matter received within the enclosure and limit the likelihood that it may spill back  
into the patient's vascular system. It also presents the device with a radially  
40 reduced profile, making it easier to withdraw the device from the patient's body  
25 without undue trauma.

45 Looking at the device in Figure 12, the system has a particular  
configuration which is unique to the present invention. In this configuration, the  
working element of the medical device is completely retained within the recess  
30 38 of the body 31 of the cover such that the distal end 36 of the cover 30 is

5 positioned distally beyond the distal end of the working element 12. In Figure  
12, at least a proximal length of the basket 12 and the body 31 of the cover are  
10 retained within the lumen of the retrieval sheath 20. This retrieval sheath radially  
compresses the proximal length of the cover such that an intermediate portion of  
5 the generally tubular wall 34 of the body 31 tightly engages a surface of the  
basket 12.

15 If so desired, the cover 30 and basket 12 may be further retracted so that  
they are both completely enclosed within the lumen of the retrieval sheath 20  
prior to withdrawing the device from the patient's vessel. This is not necessary  
20 for effective operation of the current device, though, and may be left up to the  
physician's choice during the procedure. It should also be noted that the  
configuration shown in Figure 12 may be further collapsed by withdrawing the  
25 basket 12, cover 30 and retrieval sheath 20 proximally into the deployment  
catheter C, thereby further encasing the emboli and making it easier to withdraw  
15 the device from the vascular system.

30 Figure 7 illustrates one problem which could be encountered in deploying  
a medical device retrieval system 10 of the invention across a vascular  
obstruction. The vascular obstruction in Figure 7 is typified as a stent 4 having a  
stenotic lesion 6 partially occluding the lumen thereof, but this is selected merely  
35 20 for illustration. Much the same problem could also be encountered with a variety  
of other vascular obstructions.

40 The illustrated deployment sheath 20 has a blunt distal tip 22'. Due to  
the curvature of the vessel where the stent is located, the retrieval sheath tends  
to drift upwardly toward the outside of the curve rather than easily tracking the  
25 shaft 14 of the medical device through the center of the vessel. This problem  
becomes even more pronounced if the retrieval sheath is made stiffer, such as  
45 by incorporating metallic braid into the wall of the sheath, to improve pushability.  
In some instances, it can take undue time and effort to manipulate the distal tip  
of the retrieval sheath to clear the obstruction. In addition, use of excess force  
30 or movement of the sheath to clear the obstruction risks displacing the working

5 element (not shown) of the medical device from the treatment site where it has been deployed.

10 Figures 13 and 14 illustrate two proposed solutions to ameliorate these deployment difficulties. A first solution is illustrated in Figure 13 while Figure 14 illustrates another improvement which may be used alone or in conjunction with the device of Figure 13.

15 Turning first to Figure 13, the retrieval sheath 20 shown therein includes a deployment stylet 70 slidably received in the lumen 24 thereof. This stylet has a lumen 75 within which the shaft 14 of the medical device is received, permitting the stylet to slide along that shaft 15 with the retrieval sheath 20. The stylet 70 is provided with an elongate tubular body 72 and a tapering distal tip 74. In use, the body 72 of the stylet desirably extends along the entire length of the retrieval sheath so that the proximal end of the sheath (not shown) extends proximally beyond the proximal end of the retrieval sheath so an operator may selectively control the stylet independently of the guide wire and of the retrieval sheath.

20 The distal tip 74 of the stylet tapers from its proximal end 76 to its distal end 78. At its proximal end, the distal tip has an outer diameter which approximates the diameter of the lumen 24 of the retrieval sheath at the distal end 22 thereof. As illustrated, it is not intended that the stylet 70 completely fill the lumen 24 of the sheath as that would lead to undue friction in moving the stylet relative to the sheath. The outer diameter of the sheath at the proximal end 76 of the tip 74 need only be close enough to the diameter of the distal lumen of the sheath 20 to avoid a sharp, traumatic change in diameter which would be likely to catch on vascular obstructions and hinder deployment of the sheath 20 in the vessel. The transition from the distal tip 74 of the stylet to the outer diameter of the sheath 20 can be further eased by providing the distal tip 22 of the sheath 20 with a beveled distal end.

45 The distal end 78 of the stylet's distal tip 74 has an outer diameter which more closely approximates the outer diameter of the medical device shaft 14. It is not expected that this distal end 78 be infinitely thin and track directly against the surface of the shaft 14. Again, it is sufficient that the distal end 78 of the

5 stylet be close enough to the diameter of the shaft 14 of the medical device to avoid a sharp, traumatic change in diameter which would be likely to catch on vascular obstructions and hinder deployment of the sheath 20 in the vessel.

10 When the stylet is deployed such that its distal tip 74 extends distally beyond the distal tip 22 of the retrieval sheath, the stylet provides a transition between the shaft 14 of the medical device and the distal end of the retrieval sheath 20. This makes it easier to track the shaft 14 and guide the device into position across a vascular obstruction. Figure 13 illustrates the stylet positioned such that the proximal end 76 of the distal tip 74 is positioned immediately adjacent the distal tip 22 of the retrieval sheath, but this is not necessary. If the body 72 of the stylet has a substantially constant diameter over the relevant length, the stylet can be moved distally relative to the sheath 20 such that the body extends beyond the distal end of the sheath. This will not cause any undue problem as the outer diameter of the body is desirably substantially the same as the outer diameter of the proximal end 76 of the distal tip.

20 Use of the retrieval sheath 20 with the stylet 70 can be varied. If so desired, one can use the stylet in each and every deployment of the retrieval system of the invention. However, as outlined below, use of the stylet adds an additional step to the retrieval process and its use may be reserved for those circumstances where the operator either expects to encounter a vascular obstruction or has already encountered such an obstruction.

30 In use, the stylet 70 and the cover 30 are exchangeable for one another, i.e., either the stylet or the cover may track along the shaft 14 within the lumen 24 of the retrieval sheath, but both cannot be used at the same time. Instead, one must be removed and replaced with the other. If the operator anticipates a vascular obstruction (or he or she wants to avoid exchanging devices twice if an obstruction is encountered), he or she can initially deploy the sheath 20 with the stylet. This may be accomplished by positioning the stylet 70 with respect to the sheath 20 such that the distal tip 74 of the stylet extends distally beyond the distal tip 22 of the sheath. Optimally, both the stylet and the sheath are advanced together along the shaft 14 until the distal tip 22 of the sheath is in a

5 desired position with respect to the working element of the medical device. (In  
most circumstances, this will be at a location wherein the distal tip of the sheath  
10 is near the working element, but spaced proximally therefrom, as discussed  
above in connection with Figure 11.)

5 Once the sheath is in position, the stylet 70 may be exchanged for the  
cover 30. This may be done in much the same fashion that catheters are  
15 exchanged in a typical balloon angioplasty procedure or the like. In most  
circumstances, an exchange wire will be attached to the proximal end of the  
shaft 14 of the medical device and the stylet 70 can be retracted proximally onto  
20 the exchange wire. Thereafter, the exchange wire can be disconnected and the  
cover may be advanced along the shaft 14 through the lumen 24 of the retrieval  
sheath. Using the marker band 26 of the retrieval sheath and the marker band  
25 13 of the basket 12 (for example), any final adjustments to the position of the  
sheath with respect to the working element of the medical device can be made  
15 prior to deployment of the cover.

The cover may then be moved distally with respect to the sheath 20,  
30 either by distally advancing the cover or proximally retracting the sheath. As  
noted above, this permits the body 31 of the cover to radially expand into a  
deployed configuration wherein the distal end remains distally open and the  
20 enclosure is radially expanded. The cover may then be moved distally with  
respect to the working element of the medical device and into engagement with  
35 a surface of the medical device to form therebetween an enclosure. Optimally  
(but not necessarily, depending on the configuration of the medical device and  
the shape of the cover), the cover is advanced further with respect to the  
40 25 working element until the entire working element is effectively received in the  
recess 38 of the cover. Thereafter, the retrieval sheath is moved distally with  
respect to the cover to urge the cover to collapse about the working element and  
45 tightly engage the surface of the working element to retain any debris in the  
enclosure.

30 Figure 14 illustrates another improvement of the sheath 20 of the  
invention. In this embodiment, a distal length 21 of the sheath 20 is bent at an

5 angle with respect to the body of the sheath. If a vascular obstruction is  
encountered, this distal bend will permit the operator to clear the obstruction by  
reorienting the sheath so that the distal tip 22 thereof is spaced toward the  
10 center of the vessel and away from the obstruction, whereupon the sheath can  
5 be further advanced. An angle of between about 5 and about 30° is believed to  
be sufficient for most purposes without unduly interfering with the proper  
deployment and retrieval of the cover 30. The length of the distal length 21 can  
15 be varied as needed. In most circumstances, it is envisioned that the distal  
length 21 will be 5 cm or less, with a length of 1 cm to 3 cm being most likely.  
10 As noted previously, the sheath 20 of Figure 14 with its bent distal length 21  
may be used instead of or in conjunction with the stylet 70 shown in Figure 13.

While a preferred embodiment of the present invention has been  
described, it should be understood that various changes, adaptations and  
25 modifications may be made therein without departing from the spirit of the  
15 invention and the scope of the appended claims.

## Claims

15

20

25

30

35

40

45

50

55

5

## WHAT IS CLAIMED IS:

10

1. A medical device retrieval system, comprising:

5

- a) a medical device comprising a working element carried by a flexible, elongate shaft, the working element having a proximal profile and the shaft extending proximally from the working element; and

15

10

- b) a retrieval cover slidably carried along the shaft of the medical device, the cover having a deployed configuration and being capable of being compressed into a compressed configuration for deployment, yet resiliently substantially return to the deployed configuration; the cover in its deployed configuration having a radially reduced proximal portion, a distally open distal end defining a distal opening having a maximum dimension at least as great as the maximum dimension of the proximal profile of the working element of the medical device, and an elongate internal recess defined between the proximal portion and the distal end; the cover in its compressed configuration being radially compressed inwardly toward the shaft and being distally open with the distal end defining the distal-most portion of the cover.

20

25

15

30

20

2. The system of claim 1 further comprising a retrieval sheath, the retrieval sheath being slidable along the shaft of the medical device and being positioned distally of the cover when the cover is in its deployed configuration.

35

40

25

3. The system of claim 2 where in the retrieval sheath has an inner diameter smaller than an outer diameter of the cover in its deployed configuration, the sheath being adapted to slide distally along the cover to compress the cover about the medical device.

45

30

4. The system of claim 2 wherein the retrieval sheath has a body and a distal tip comprising a distal length of the retrieval sheath, the distal tip being bent at an angle of between about 5 and about 30° with respect to the body.

50

55

5

5. The system of claim 4 wherein the distal tip is between about 1 cm and about 5 cm in length.

10

6. The system of claim 4 wherein the distal tip further comprises a radiopaque marker band.

5 7. A medical device retrieval system, comprising:

15

a) a medical device comprising a working element carried by a flexible, elongate shaft having an outer diameter, the working element having a proximal profile and the shaft extending proximally from the working element;

20

10 b) a retrieval sheath being slidable along the shaft of the medical device, the retrieval sheath having a beveled distal end with a distal lumen;

25

15 c) a deployment stylet slidable along the shaft of the medical device, the deployment stylet having a distal tip tapering distally from a first diameter approximating a diameter of the distal lumen of the sheath to a second diameter more closely approximating the outer diameter of the medical device shaft, providing a transition between the shaft of the medical device and the distal end of the retrieval sheath when the deployment stylet is positioned such that the distal tip extends distally beyond the distal end of the retrieval sheath; and

35

20 d) a retrieval cover slidable along the shaft of the medical device and being exchangeable for the stylet therealong, the cover having a deployed configuration and being capable of being compressed into a compressed configuration for sliding within the lumen of the retrieval sheath yet resiliently substantially return to the deployed configuration; the cover in its deployed configuration having a radially reduced proximal portion, a distally open distal end defining a distal opening having a maximum dimension at least as great as the maximum dimension of the proximal profile of the working element of the medical device, and an elongate internal

40

25

45

30

50

55

5

recess defined between the proximal portion and the distal end; the cover in its compressed configuration being radially compressed inwardly toward the shaft and being distally open with the distal end defining the distal-most portion of the cover.

10

- 5 8. A retractable medical device system, comprising:
- a) a medical device comprising a working element carried by a flexible, elongate shaft;
- 15 b) a retrieval cover slidable along the shaft of the medical device, the cover having a radially reduced proximal portion, a distally open distal end and an elongate tubular wall extending therebetween and defining a recess; the working element of the medical device being completely retained within the recess of the cover such that the tubular wall extends distally beyond the medical device; and
- 20 c) a retrieval sheath, the retrieval sheath having a lumen and being slidable with respect to both the medical device and the cover, at least a proximal length of the working element of the medical device and the cover being retained within the lumen of the retrieval sheath, the retrieval sheath radially compressing the proximal length of the cover such that an intermediate portion of the wall tightly engages a surface of the medical device.
- 25 9. A method of retrieving particulate or other foreign material within a channel of a patient's body, comprising:
- a) providing a medical device having a working element and a flexible, elongate shaft adapted to follow a path within the channel;
- 40 b) a distally open cover slidable with respect to the shaft; and a retrieval sheath moveable with respect to the cover and the shaft;
- 45 c) positioning the medical device within the vessel to engage a wall of the channel and trap the material within the channel, the cover and the retrieval sheath being spaced proximally of the working element along the shaft of the medical device, the cover being radially compressed within the lumen of the retrieval sheath such
- 50

55

5

that it has a distally open distal end and a wall defining a recess,  
the wall engaging an inner surface of the retrieval sheath;

10

c) moving the cover distally with respect to the retrieval sheath,  
thereby permitting the cover to radially expand into a deployed  
configuration wherein the distal end remains distally open and the  
enclosure is radially expanded, the cover expanding radially  
outwardly into the deployed configuration without having to invert  
on itself;

15

5

d) moving the cover distally with respect to the medical device and  
into engagement with a surface of the medical device to form  
therebetween an enclosure;

20

10

e) moving the retrieval sheath distally with respect to the cover to  
urge the cover to collapse about the medical device and tightly  
engage the surface of the medical device.
